As a third party administrator of the Central Bull Test Program, the Virginia Beef Cattle Improvement Association (BCIA) works to serve its two purposes of: 1) to foster the improvement of beef cattle in Virginia through improved genetics and management with major emphasis placed on selection criteria for traits of economic importance, and: 2) to carry on educational and promotional work in connection with the production of improved beef cattle.

With the above mission in mind, BCIA sets forth strict requirements for bulls to be tested in one of their programs. Some of the eligibility requirements include: bulls meeting evaluated YW EPD requirements based on breed VQA requirements; minimum frame score of 5.0; structural and reproductive soundness; disposition; and pre-weaning and vaccination programs.

The bulls will be on test for 112 days. During this testing period, weights will be taken as well as hip height measurements, ultrasound data collection, and semen testing. At the end of the test, the top two-thirds of the bulls on test will be selected for the sale. This selection takes into account basic requirements listed above along with the bulls own performance and EPDs for several traits.

“For many years we didn’t do semen checks on yearling bulls at the test stations to avoid disqualifying bulls that would not pass just because they were immature. Reproductive exams on bulls included measuring scrotal circumference and an examination of the reproductive tract including a rectal exam,” stated Dr. Dee Whittier, Extension Veterinarian for the VA/MD Regional College of Veterinary Medicine.

In the 2008 – 2009 test year, as a result of a bull buyer survey, the BCIA test program made enhancements towards its bull buying program. Some of those improvements include: a full semen evaluation on all senior bulls (conforming to the Society of Theriogenology guidelines), genetic defect testing, and breeding guarantees. However, this testing did have a big issue. Whittier explained that “One of the problems with doing breeding soundness exams on yearling bulls is that some of them are just not mature enough. This results in too high a number of abnormal sperm cells to pass the test. Some bulls that fail at 12, 13 or 14 months will pass fine at 15, 16 or 17 months.”

At the end of each test, all bulls receive a breeding soundness exam and all senior bulls receive a full semen evaluation. Every bull must pass a breeding soundness evaluation off-test. The exam includes semen evaluation for Senior bulls, internal palpation, scrotal circumference measure and penile inspection with electro-ejaculator. Minimum scrotal measurement is 32 cm for bulls less than 15 months of age, and 33 cm for bulls 15 to 18 months of age. This is 2 cm more stringent than the Society for Theriogenology recommendations. Senior bulls are given a minimum of two opportunities to pass the semen evaluation (off test and again pre-sale).
Based upon this suggestions from bull buyers, the BCIA test committees has set forth high standards for bulls to complete in order to sell (see Table 1 for complete requirements). Bulls not meeting the minimum requirements are scratched from the sale.

To be classified as a Satisfactory Potential Breeder requires a satisfactory Physical Examination and minimum values for Scrotal Circumference, Motility and Morphology. Any bull not meeting minimums is classified as either an Unsatisfactory Potential Breeder or classification may be deferred at the discretion of the evaluator.

Dr. Dee Whittier, Professor of Large Animal Clinical Sciences at the Virginia Maryland Regional College of Veterinary Medicine, administers the breeding soundness exams for the BCIA bull test stations. Dr. Whittier explains what is evaluated in the breeding soundness exam below:

The BSE is performed at a single examination, although repeated examinations may be required in some cases. The BSE consists of the following procedures.

- **Physical examination**- The bull is examined in a systematic way for any problem that would hamper his ability to impregnate cows. This examination may be rather brief or more detailed if there is a reason to suspect that there is a problem with any body system. Common areas for problems are abnormalities of the feet and legs or the eyes. A bull cannot locate and mate cows unless his feet and legs are sound. Structural faults, such as sickle hocks and post legs, can cause sore feet and stresses on tendons and joints that affect the bull's mobility. Legs and joints should be free from any swelling or old injuries. Cracked hooves, corns and long hooves also slow the breeding ability of bulls. Long hooves and corns should be dealt with four to six weeks prior to the breeding season. This will give the bull time to recover and have sound feet before he is turned out for breeding. Eyes should be clear and free of injuries or diseases. Pink eye or cancer eye may hinder a bull's vision and reduce his breeding effectiveness. Such problems may
also allow him to be dominated by other bulls and diminish his ability to cover the desired number of cows.

As part of the physical examination a body condition score is assessed. The system used is the 9-point-scale system. Bulls that are either overconditioned or underconditioned would be expected to have lower fertility.

- **Reproductive tract examination** - The bull reproductive tract consists of the scrotum, testicles, penis, prepuce and their associated structures. These structures can be examined externally both visually and by manual palpation. However, examination of the penis and entire prepuce typically requires the extension of the penis using an electroejaculator. There are also a number of internal portions of the reproductive tract which require an exam per rectum. The arm of the examiner is inserted through the anus of the bull into the rectum. Because of the flexibility of the rectum the internal portions of the penis, the internal parts of the vas deferens and the accessory sex glands (the prostate and seminal vesicles) can be manually examined.

- **Measurement of Scrotal Circumference (SC)** - Measuring scrotal circumference is a crucial part of the BSE. Scrotal circumference has been determined to be the measurement that best predicts the output of sperm cells for bulls when multiple collections by artificial vagina are not available. The measurement technique involves the use of a circular tape. This measure is useful because there is a correlation between the scrotal circumference and the volume of semen-producing tissue that the bull possesses. Since SC increases with the age and weight of the bull the circumference must be interpreted in light of the bull’s age. Scrotal Circumference has been determined to be one of the best predictors of bull fertility.

- **Semen collection and examination** - Although semen could theoretically be collected using an artificial vagina, in most cases the difficulty in training bulls to use this system makes it impractical. Instead, the semen sample is collected using a device called an electroejaculator. This device employs a probe that is inserted rectally into the bull. The probe has electrodes that conduct tiny amounts of electricity to the nerves that run through the bottom of the bull's pelvis. This stimulation results in the bull achieving an erection and finally ejaculating semen. An experienced veterinarian or reproductive physiologist should determine semen quality. An examination of the reproductive tract may indicate possible abnormalities in semen quality. Bulls exhibiting normal physical capabilities may still be incapable of settling cows because of poor quality semen.
  - Motility: Motility can be estimated by observing the mass movement of a concentrated sample of semen. Semen graded as very good has vigorous swirls; that graded good has slow swirls. Poor semen motility indicates limited or no motility. Semen should have a minimum of 30 percent vigorous, motile sperm when diluted and viewed through the microscope. It is important that motility is not hindered prior to the motility score.
observation. Temperature, shock and other factors can greatly interfere with motility scores.
- Morphology: There is considerable evidence that increased abnormalities of sperm cells are associated with poor conception rates. Abnormalities are classified as primary and secondary conditions.

Bulls which fail to pass the BSE are assumed to be subfertile. Certainly they may sire some calves but would not be expected to perform well in a typical breeding setting. Bulls who fail the BSE at one point may later be capable of passing. Evaluators usually attempt to predict such outcomes and thus classify bulls as Unsatisfactory or a Deferred status.

“Now the bull breeders have decided they are willing to deal with the consequences of eliminating some bulls on semen checks just because of immaturity. This practice will also eliminate, of course, bulls that truly are infertile. In fact, the bull breeders have chosen to sacrifice some on their part to provide bull buyers with a more fertile product,” discussed Whittier.

The BCIA Bull Test Program and its consignors want the bull buyers to know and understand what the expectations and requirements are of each of the bulls that are eligible for sale. Because of these standards, BCIA only sells the top 2/3 of the bulls that meet or exceed these requirements.

BCIA and the Central Virginia Bull Test Program would like to invite everyone to its 33rd Annual Southwest Virginia Performance Tested Bull Sale on March 24th, 2012 at the Umberger Sale facility in Wytheville, VA at 12:00 noon. For additional information on the bulls currently on test, please visit our website at www.bcia.apsc.vt.edu or call the BCIA office at 540-231-9159.
